

# Syrning og koagulering i mozzarella produktion

Ulf Mortensen

Principal Scientist

Global Cheese Application

CHR HANSEN

*Improving food & health*

# Mozzarella is the biggest category in the commercial cheese market

**23%\*** of all cheese produced is Mozzarella type cheese.  
That's **5 Million MT** per year!

For every mozzarella launched in supermarkets **8 more new products\*\*** are launched with mozzarella inside

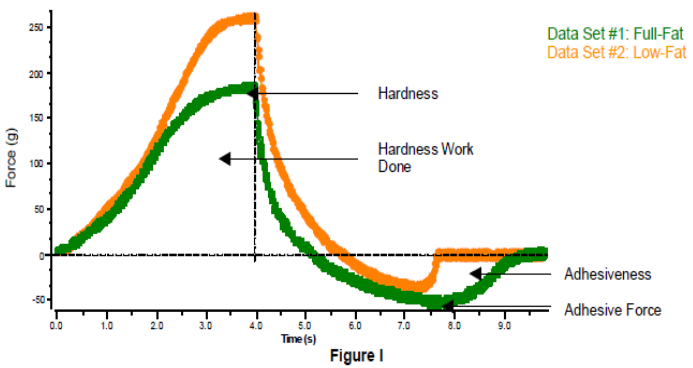

Mozzarella Industrial use is expected to rise by **3.4% p.a.** by 2017

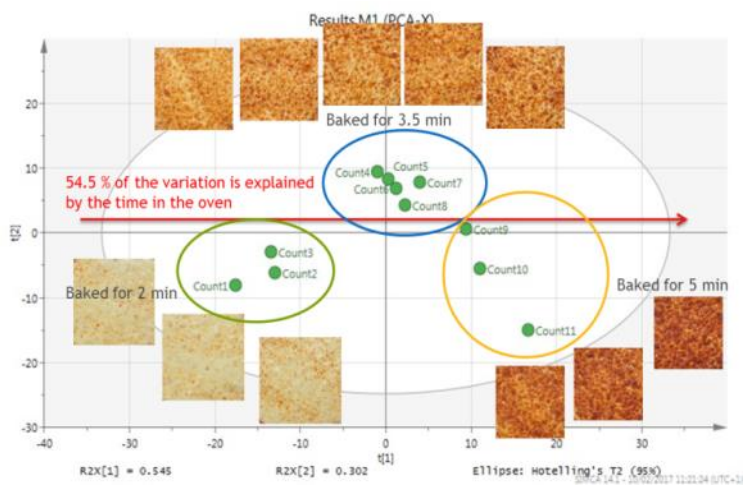

# Functional properties refer to the characteristic behavior of the cheese when it is shredded, sliced or heated

Functional properties can roughly be divided into **unheated** and **heated** functional properties

## Unheated

## Heated

- 2 Coagulants for Pasta filata
- 3 Cultures for Pasta filata
- 4 Optimized Pasta filata process

# Cheese Making Process – Pasta Filata

# Example of Pasta Filata setup in an industrial plant

# A global approach

# Let's briefly cover the role of coagulants in cheese making

## Coagulation

Efficient coagulation consists of mainly two things – time to coagulate and optimizing cheese yield. Coagulation is impacted to a large extent by the specific coagulant, but also the milk preparation in scope.

## Ripening

Choice of coagulant plays a role also in the ripening of the cheese. This links to the level of proteolysis delivered by the coagulant that impacts flavor and texture development as well as other key functionalities.

## Whey

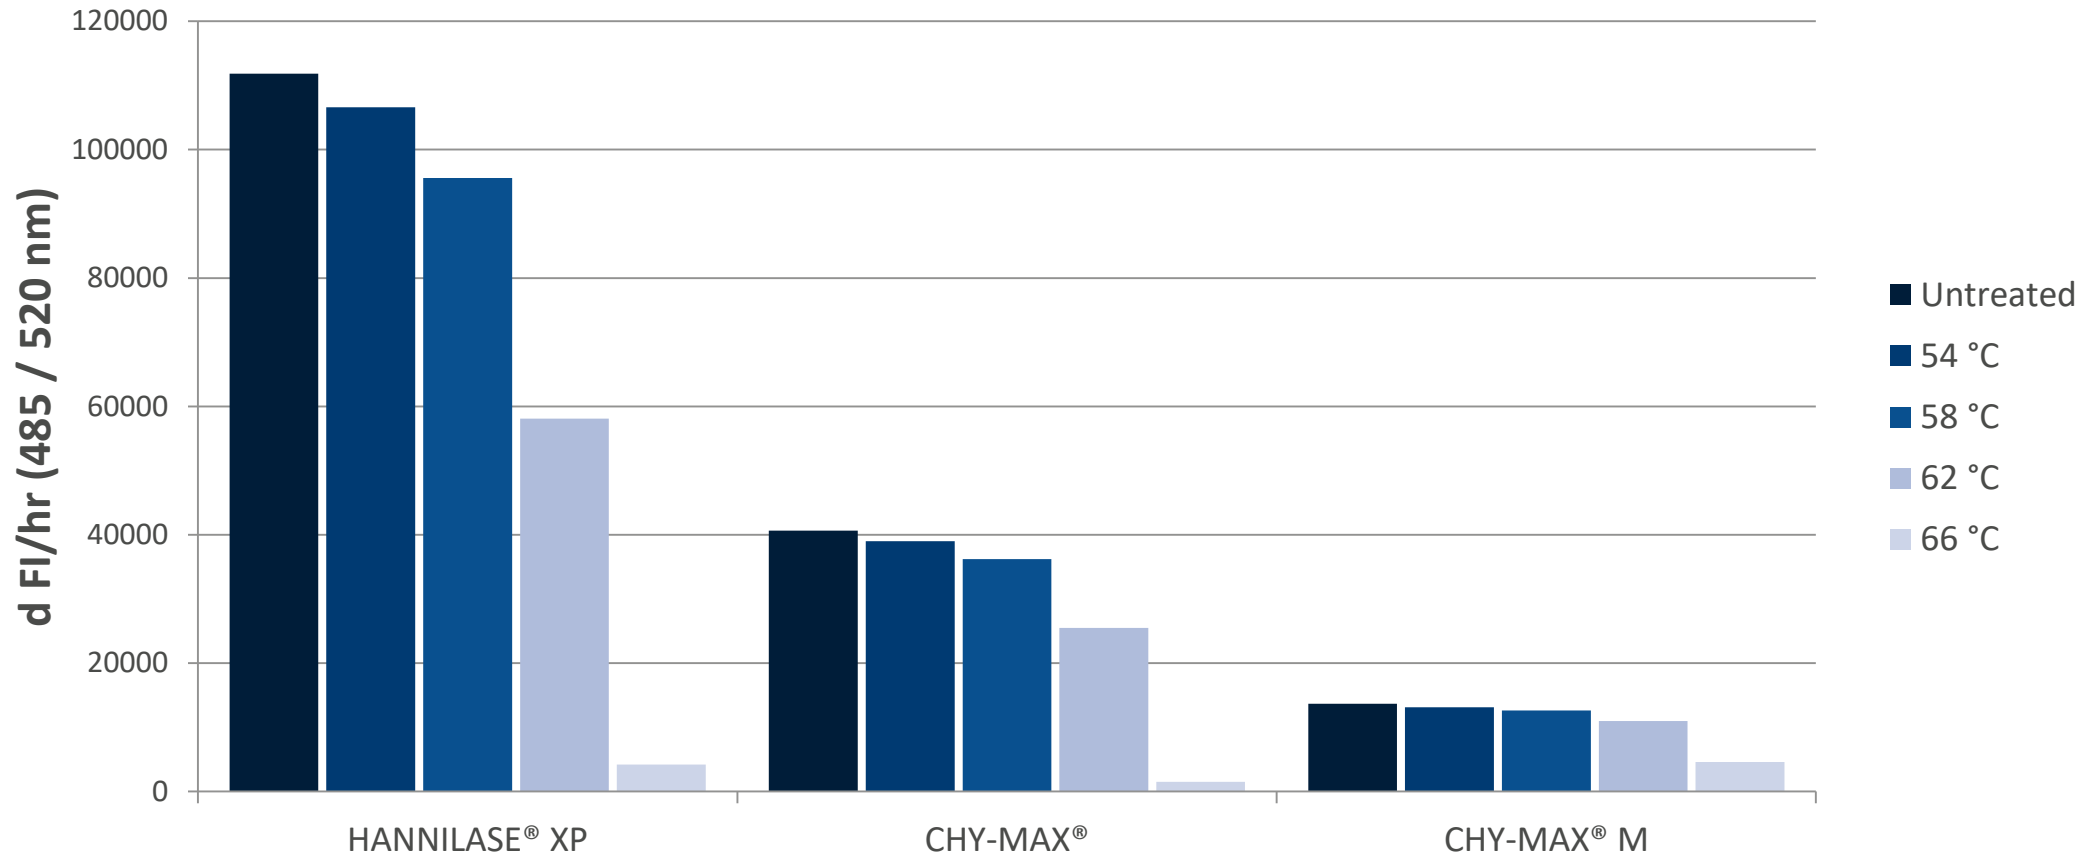

Focus on whey is ever increasing. The choice of coagulant impacts among others the breakdown of whey proteins into small low-value peptide fractions. Also, the ability to inactivate the coagulant is important.

# Heat treatment has tremendous impact on proteolytic activity after 5 min at different temperatures

Residual proteolytic activity (pH 5.2)

# Managing and/or reducing the protein breakdown is key to ensure optimal cheese functionality

**CHY-MAX® M ensures the highest level of intact protein throughout shelf life**

# Optimal texture for shredding and slicing

## Coagulant choice for Mozzarella

Coagulant	Advantages	Disadvantages
Hannilase <sup>®</sup> (Mucor coag.)	Low purchase price Fastest ripening	High cost in use Low cheese yield High residual proteolysis
Chymax <sup>®</sup> (Bovine chymosin)	Good cheese yield Good ripening	Some residual proteolysis Not the highest cheese yield
Chymax <sup>®</sup> M (Camelus chymosin)	Highest cheese yield Low dependency of pH & CaCl <sub>2</sub> Low cost in use	Very little ripening
Chymax <sup>®</sup> Special (Camelus chymosin)	Highest cheese yield Some ripening Low cost in use	

# Cutting the curd at the right firmness is very important for optimizing production output and quality

Traditional firmness appreciation

CHYMOgraph®

The CHYMOgraph® is a patented Chr. Hansen tool developed in 2011, in cooperation with a French Dairy School

Coagusens™

Coagusens™ is a patented equipment developed by Rheolution. Chr. Hansen has an agreement to distribute product globally.

An industrial version of the CHYMOgraph®

*Improving food & health*

# The CHYMOgraph<sup>®</sup> and the CoaguSens<sup>™</sup> delivers graphic indicators to help optimize coagulation...

# CoaguSens™ is a tool to reduce variability and optimizing yields

## Network speed and curd firmness development

## Cutting firmness as function of batches

# Sensitivity to Coagulation Temperature and to milk pH

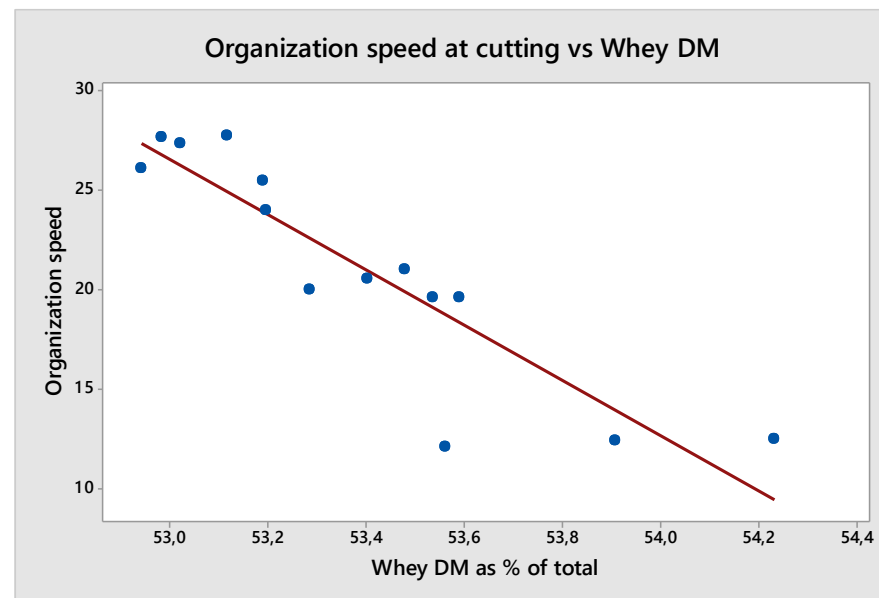

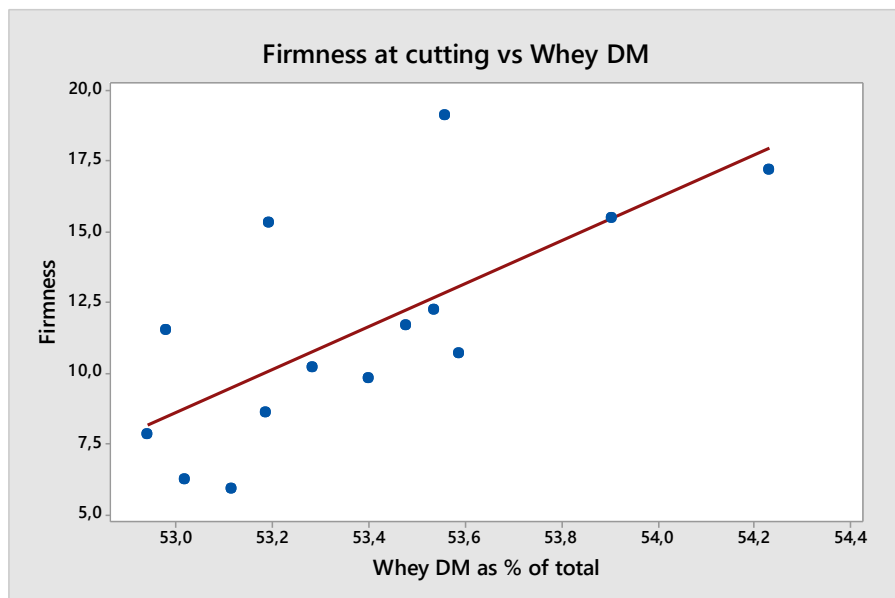

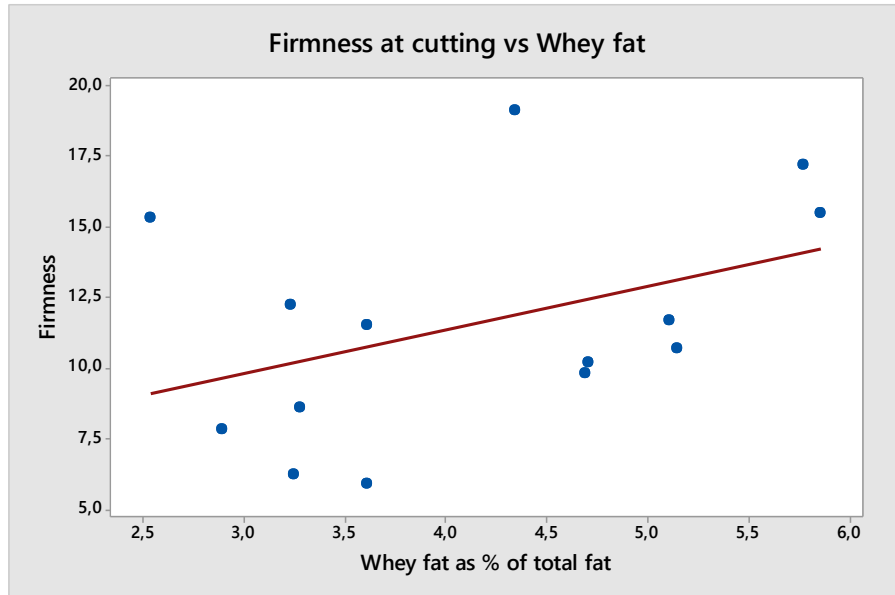

# Field data - Curd firmness of different trials

# Yield optimization Correlation graphs

## Effect of increased coagulant dose and reduced coagulation time

- Faster gel organization speed – better gel organization - less losses to the whey
- Faster immobilization of culture strains and phage – less ‘sub-critical’ phage attack – less moisture variation
- Better effect on reducing losses of fat and TS by optimizing on organization speed rather than firmness

# Cultures

3

# Demineralization happens as a consequence of acidification

# Stretching

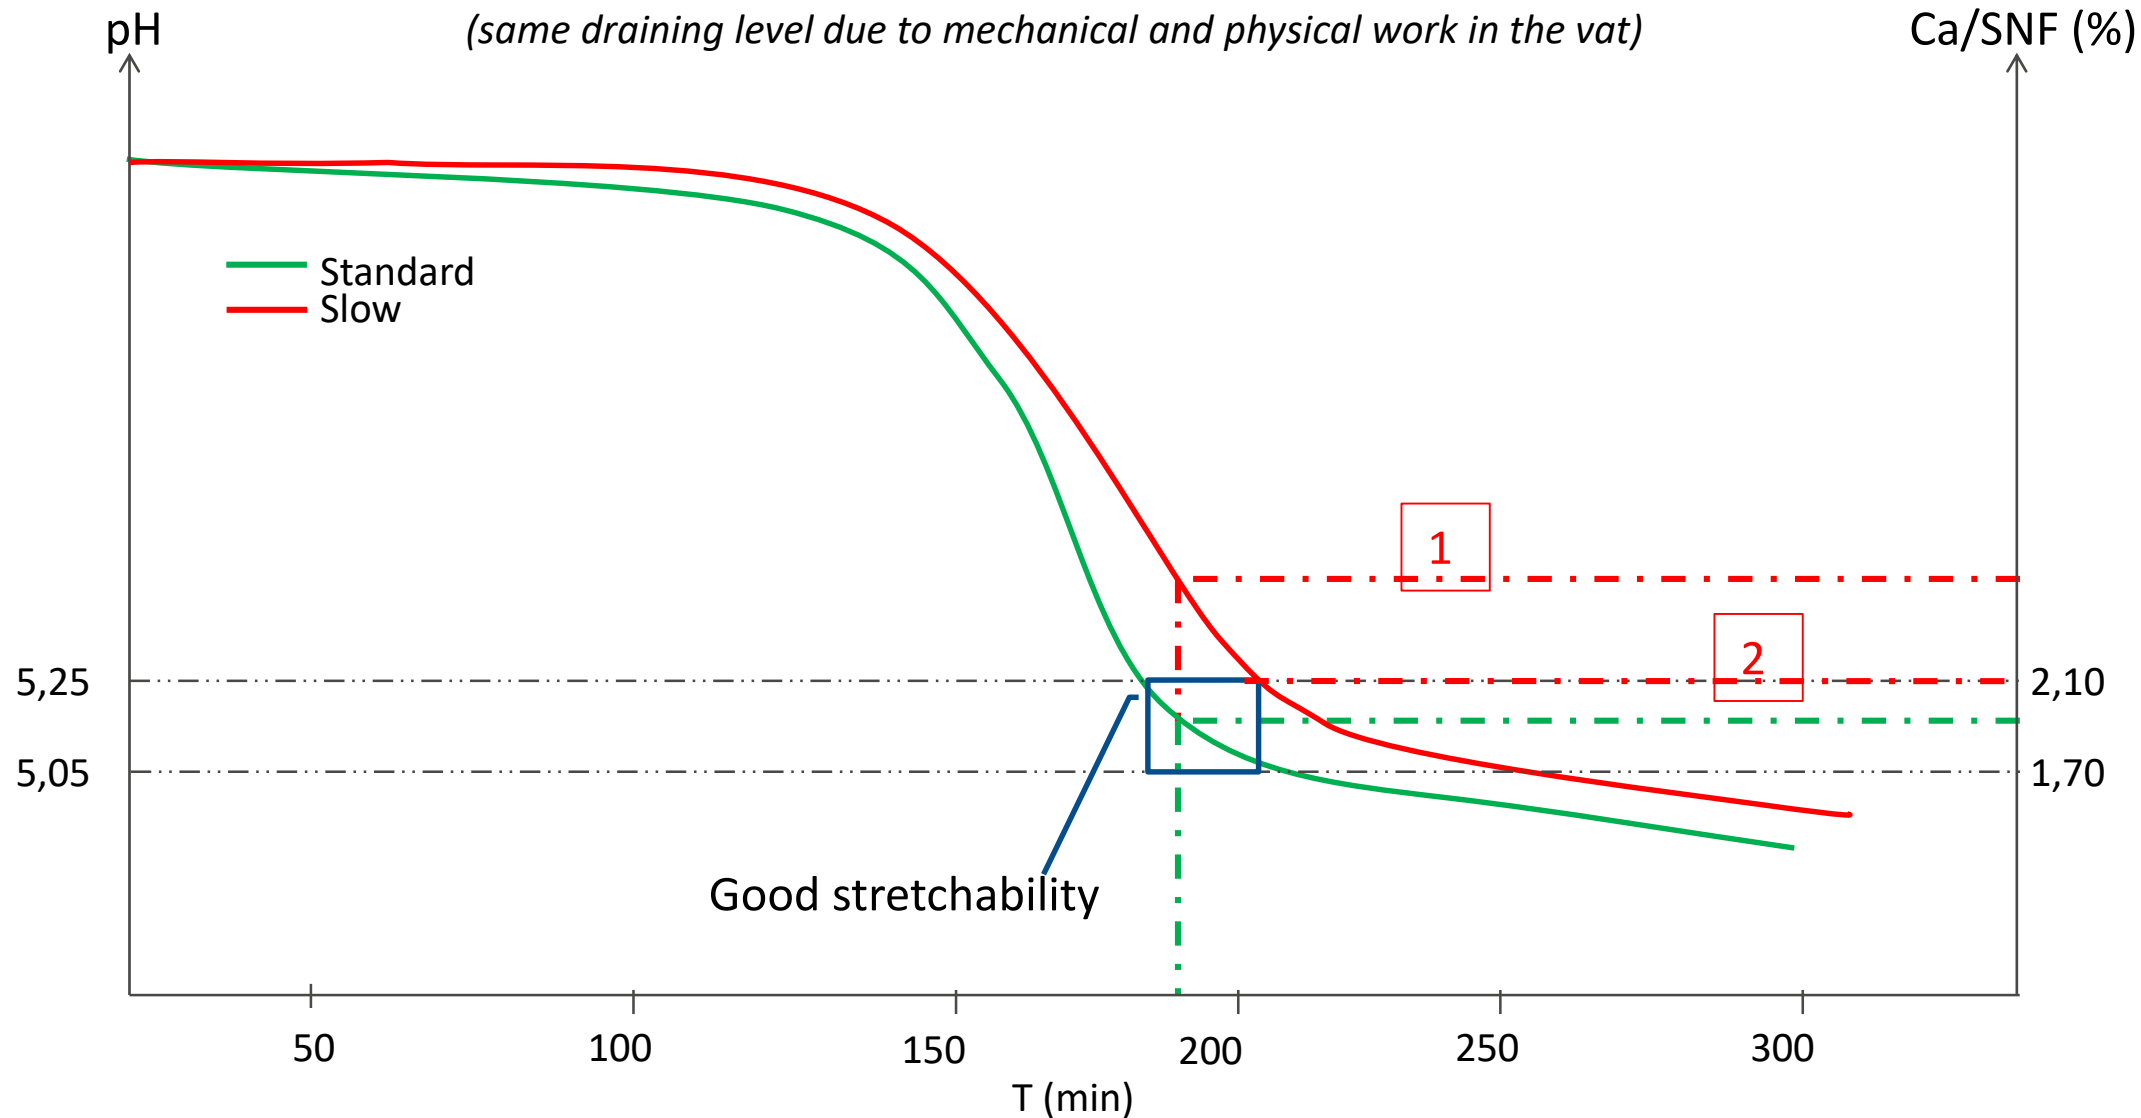

'Bad' Stretch

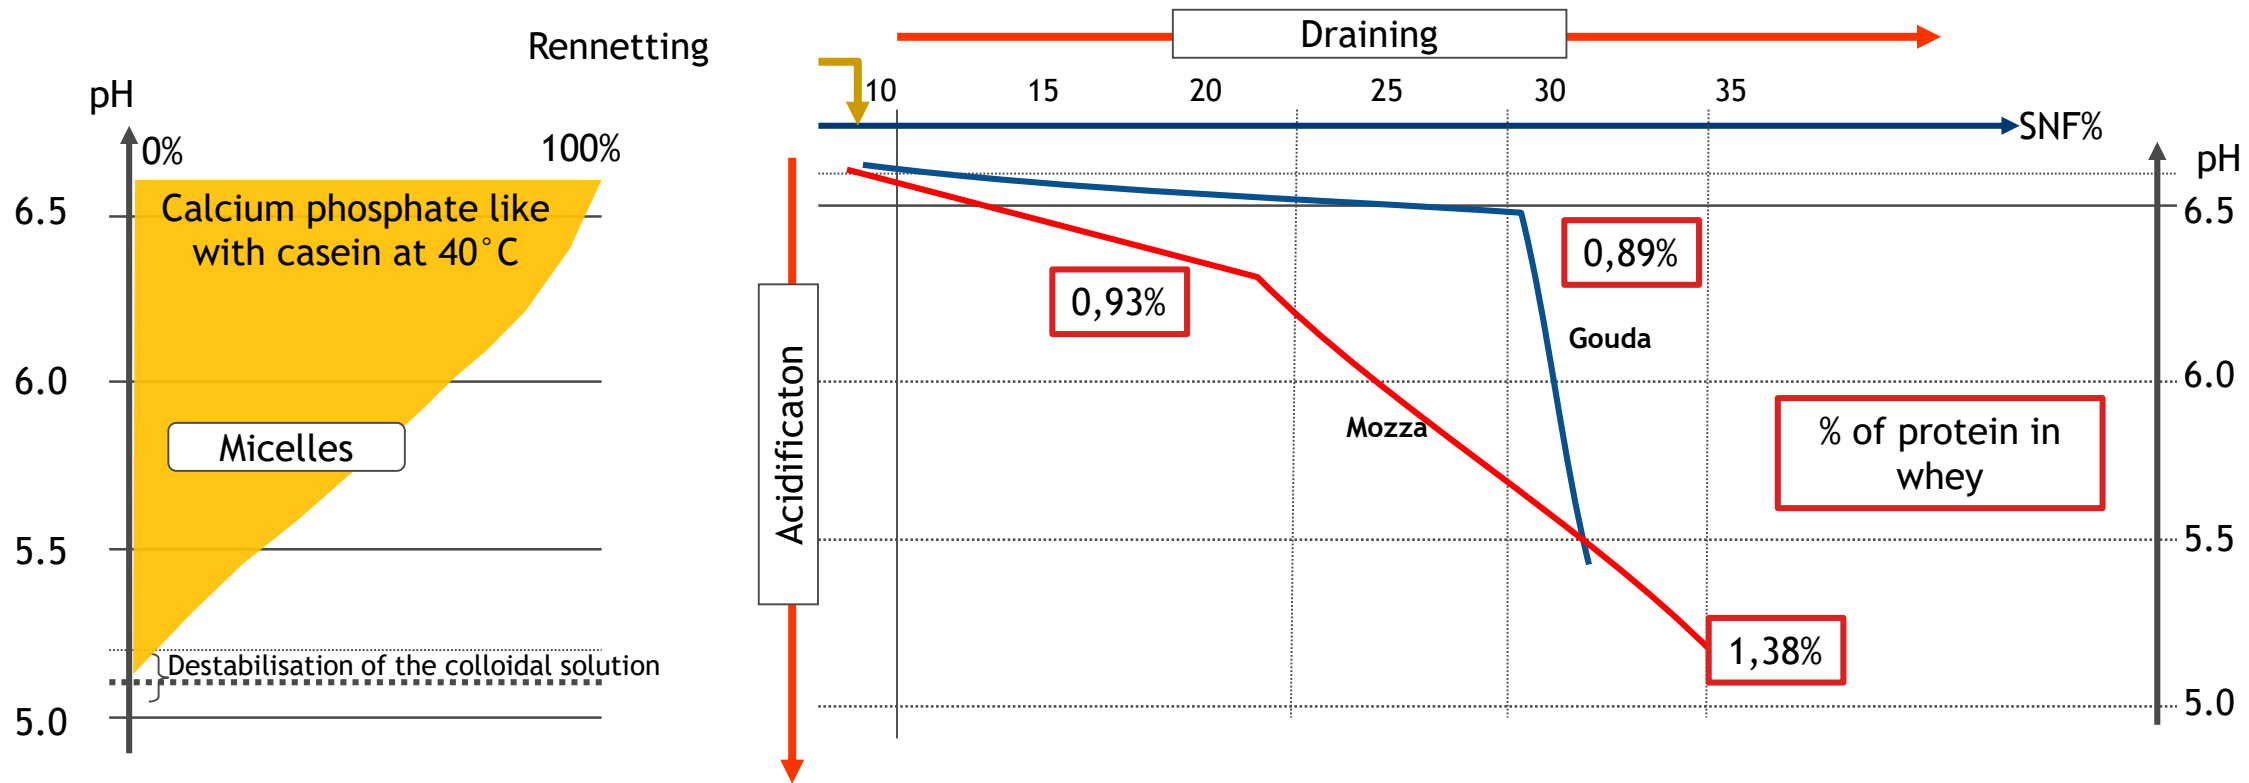

'Good' Stretch

Consequence of inconsistent acidification  
(same draining level due to mechanical and physical work in the vat)

1. Stretching is more difficult due to insufficient demineralization level
2. Stretching is more difficult due to higher dry matter
3. Less proteolysis (because of higher buffer capacity and/or dry matter) lead to less meltability and flavor in mozzarella

# Relative importance of draining and acidification during cheesemaking

**Draining in vat**

Gouda : 90-92%

Mozza : 70-72%

**Acidification in vat**

Gouda : 20%

Mozza : 28%

# Relative importance of draining and acidification rate during cheesemaking (Standard Mozzarella-LMPS and optimized process)

## Effect of increased culture dose and reduced milk ripening time

- More competition against NSLAB
- Less advantage for phage's generation time/burst size
- Later, but faster acid development – higher solids retention

# Cheese making profiles

# Changes in the cheese making profile

## Typical

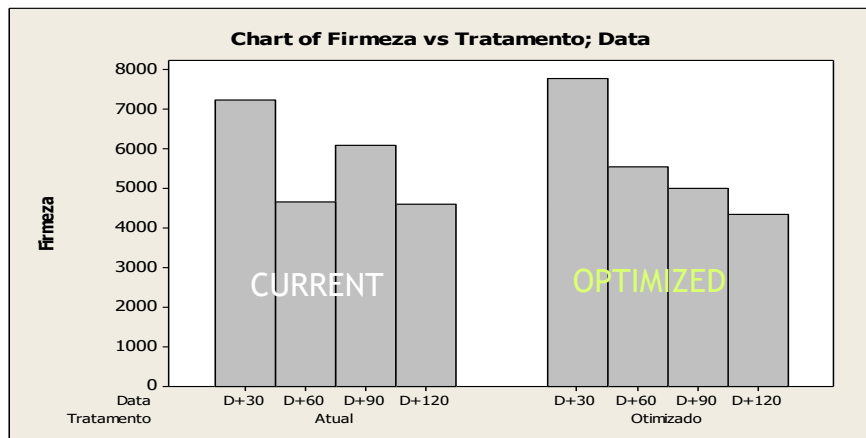

- Culture dose: 500-1000U DVS in 20.000L
- Coagulant
  - Microbial: 3500 IMCU/100L
  - Chymosin: 2000 IMCU/100L
- Set/Scald: 35C/39C
- Milk ripening: 45-60 min
- Vat time: 152 min
- Belt time: 95 min
- Total time: 247 min

## Optimized

- Culture dose: 2000U DVS in 20.000L
- Coagulant
  - Chymosin: 2500-3000 IMCU/100L
  - Chymax M: 2500 IMCU/100L
- Set/Scald: 34C/40-40,5C
- Milk ripening: 5-10 min
- Vat time: 127 min
- Belt time: 75 min
- Total time: 202 min

**Total yield increase: 1-1,2%**

# Functionality

Firmness

Stretching

Oiling off

Melting point

## In summary

- Choice and dosage of coagulant is crucial for yield and functional properties
- Dosage of cultures have a strong impact on yield
- Using an optimized process can give 1-1,2% higher yield without affecting the functional properties

**Thank you for your attention**
